Risk of Exposure

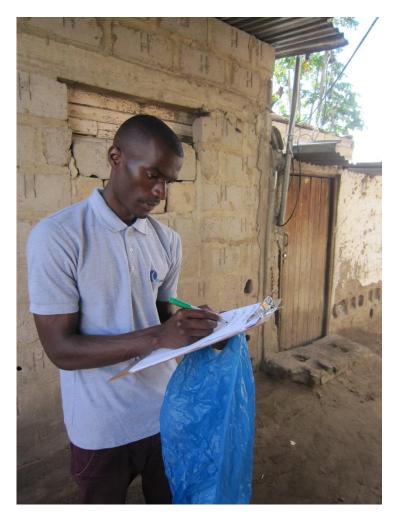

Which pathways pose the greatest risk of exposure?

<u>Confused</u> designed by <u>Jessica Look</u> for The Noun Project

Overview The SaniPath Exposure Assessment Tool

- Assesses relative public health risks related to poor sanitation and FSM
- Guides data collection & analysis
- Can help prioritize programs and policy

Methods

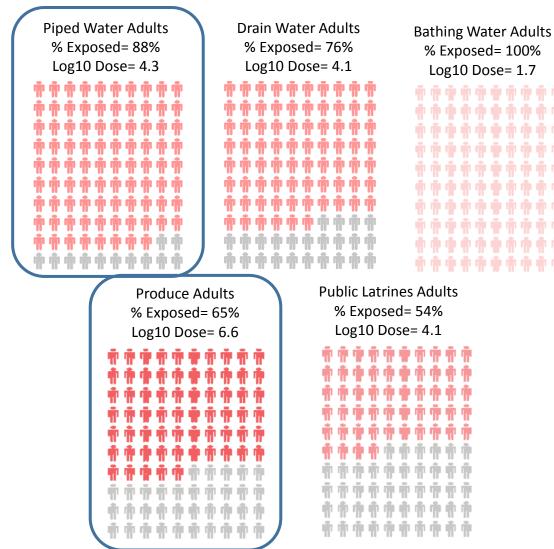

SaniPath Field and Analysis Methods

- Field Work
 - Environmental Samples
 - Behavioral Surveys
 - GPS data
- Lab
 - Test samples for *E. coli*
- Analysis
 - Estimates % population exposed and mean dose

SaniPath Results

People plots show variation across pathways within a neighborhood

Research Questions

- How consistent are the results of a SaniPath exposure assessment?
- How do fecal exposure pathways vary across neighborhoods in different cities?

Question 1

Examining the Consistency of SaniPath Results

- 1. Is the risk ranking of pathways similar?
- 2. Are the risk estimates similar (percent of exposed population and magnitude of exposure)?
- 3. If different, where are the differences and why?

Comparing Simultaneous Parallel Deployments Two teams collect data simultaneously in Chorkor, Accra, Ghana

.....

Public Latrine Surface Percent Exposed = 89 % Log10 Dose= 1.88

Percent Exposed = 83 % Log10 Dose= 1.87

Drain Percent Exposed = 72 % Log10 Dose= 7.07		Produce Percent Exposed = 92 % Log10 Dose= 7	Piped Water Percent Exposed = 67 % Log10 Dose= 5.17	I

Results look nearly identical-suggesting good consistency

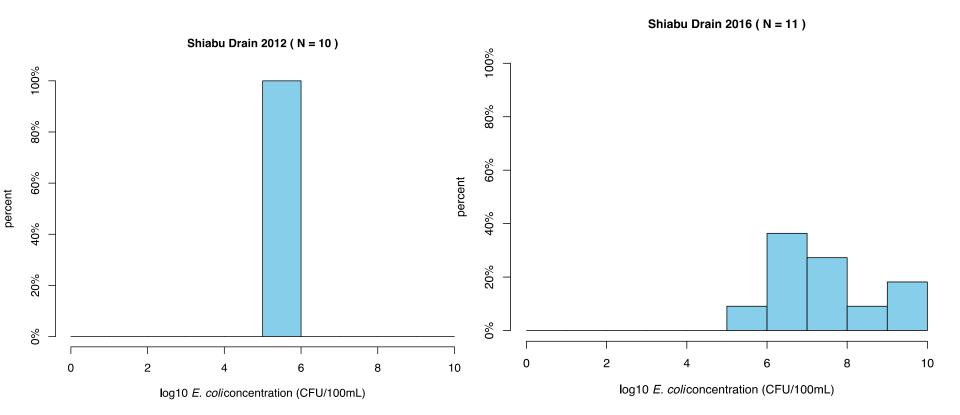

Comparing Deployments from Two Different Years Comparing 2012 and 2016 results for pathways in Shiabu, Accra, Ghana

Risk profiles for drains are different Other risk profiles are nearly identical

2012

A Deeper Look Comparing Drain results from Shiabu in 2012 and 2016

E. coli concentrations in drain samples were at upper limit of detection in 2012.

Dilutions of drain samples were adjusted in 2016 and *E. coli* concentrations were quantified more accurately

Question 2 Three pathways, three cities

Greatest variability was in drain pathway.

Drains

Moderate fecal contamination but high % exposed to drinking water

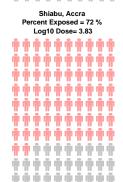

Drinking Water

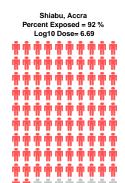

Produce is consistently highly contaminated, but % exposed population varies by city

Produce

Shiabu, Accra

	Percent Exposed = 70 % Log10 Dose= 7.56

Question 2 Drains in Accra, Vellore, and Maputo

Accra, Ghana

Vellore, India

Maputo, Mozambique

Summary

- Fecal contamination varies across pathways in a single neighborhood
- Good consistency in risk profiles
- Exposure to fecal contamination varies across pathways for 3 different cities

Information on geographic and pathway differences can be used:

1. For **advocacy** to raise awareness about the risks from poor sanitation and FSM

2. To **target investments** to areas/pathways of greatest risk.
